Abstract

We consider low-rank approximation of affinely structured matrices with missing elements. The method proposed is based on reformulation of the problem as inner and outer optimization. The inner minimization is a singular linear least-norm problem and admits an analytic solution. The outer problem is a nonlinear least squares problem and is solved by local optimization methods: minimization subject to quadratic equality constraints and unconstrained minimization with regularized cost function. The method is generalized to weighted low-rank approximation with missing values and is illustrated on approximate low-rank matrix completion, system identification, and data-driven simulation problems. An extended version of the paper is a literate program, implementing the method and reproducing the presented results.

Keywords: low-rank approximation, missing data, variable projection, system identification, approximate matrix completion.

1 Introduction

The paper describes a solution method for matrix structured low-rank approximation, i.e., approximation of a given matrix by another matrix whose elements satisfy certain predefined relations (matrix structure) and whose rank is less than or equal to a predefined value. The combination of matrix and low-rank structure makes structured low-rank approximation a tool for data modeling. Low-rank property of a matrix is equivalent to existence of an exact low-complexity linear model for the data. Moreover, the rank of the matrix is related to the complexity of the model. The structure, imposed on the approximation, is related to properties of the model. For example, Hankel structure corresponds to time-invariance of a linear dynamical model for the data. A tutorial exposition of the subject with an emphasis on applications in systems theory, control, and signal processing, is given in [12, 14].

A novel feature of the low-rank approximation problem, considered in this paper, is that elements of the data matrix can be missing (not specified). Missing data may occur in practical applications due to malfunctioning of measurement device, communication channel, or storing device. In such cases, the most common strategy is to collect a complete data record by repeating the data collection experiment. In other applications, however, the missing data problem is intrinsic and can not be avoided by repeated experiments. Two such applications reviewed in Subsection 1.2 and further illustrated by numerical examples in Section 5 are recommender systems and data-driven simulation.

Although structured low-rank approximation and approximate low-rank matrix completion (missing data estimation in low-rank matrices) are independently active research topics, the combined problem of missing data estimation in affine structured low-rank matrices has not been considered before. Both the structured low-rank approximation and approximate matrix completion problems are nonconvex optimization problems that in general admit no analytic solution, see [8]. Therefore, in both domains local optimization and convex relaxation heuristics are used as solution techniques. In this paper, we use the local optimization approach.

Structured low-rank approximation has been studied in the literature from different viewpoints: numerical algorithm for computing locally optimal or suboptimal solutions, statistical properties of the resulting estimators, and applications. From a numerical point of view, the main challenge is to achieve fast and robust computational methods that can deal effectively with large data sets. From a statistical point of view, the main challenge is to establish conditions for consistency and efficiency of the methods. Our objective in this paper is different: we aim to unify as
many data modeling applications as possible and derive a single algorithm that solves them. Of course, this goal can be achieved by brute force optimization. The challenge is to discover and use effectively the structure of the problem. In the general problem considered, this structure is a separation of variable with analytic solution over one set of variables. This approach is related to the variable projection method [9] used in [18].

The solution method proposed in the paper has computational complexity $O(n^3)$ per iteration, where $n$ is the number of columns of the data matrix. It is applicable to general affine structured matrices with missing data, however, it is unsuitable for large scale applications. In special cases, such as unstructured matrices with missing data or mosaic-Hankel structured matrices without missing data, there are efficient $O(n)$ methods. We conjecture that an efficient $O(n)$ implementation of the algorithms in the paper is possible in the case of mosaic-Hankel matrices with missing data.

1.1 Problem formulation

We denote missing data values by the symbol NaN (“not a number”). The considered low-rank approximation problem is: Given a data vector $p \in (\mathbb{R} \cup \{ \text{NaN} \})^{n_r}$,

$$\begin{align*}
\text{minimize} & \quad \text{over } \hat{p} \in \mathbb{R}^{n_r} \sum_{i \mid p_i \neq \text{NaN}} (p_i - \hat{p}_i)^2 \\
\text{subject to} & \quad \text{rank } (\mathcal{S}(\hat{p})) \leq r, \quad (\text{SLRA})
\end{align*}$$

where

$$\mathcal{S} : \mathbb{R}^{n_r} \to \mathbb{R}^{m \times n}, \quad \text{defined by } \mathcal{S}(\hat{p}) = S_0 + \sum_{i=1}^{n_r} S_i \hat{p}_i, \quad (\mathcal{S})$$

$$\langle \text{default s0} \rangle \equiv \begin{cases} 0 & \text{if } \text{exist}(\text{s0}) \mid \text{isempty(s0)}, \text{s0} = \text{zeros(mp, n)}; \end{cases} \quad (7.11b)$$

is the matrix structure—an affine function from the structure parameter space $\mathbb{R}^{n_r}$ to the set of matrices $\mathbb{R}^{m \times n}$. With $\mathcal{I}$ denoting the vector of indices of the given values $\{i \mid p_i \neq \text{NaN} \}$ and $p_\mathcal{I}$ denoting the subvector of $p$ with indices in $\mathcal{I}$, the approximation criterion can be written as

$$\sum_{i \in \mathcal{I}} (p_i - \hat{p}_i)^2 = \| p_\mathcal{I} - \hat{p}_\mathcal{I} \|^2_2.$$

Without loss of generality, we assume throughout the paper that $r < m \leq n$. Using the kernel representation of the rank constraint

$$\text{rank } (\mathcal{S}(\hat{p})) \leq r \iff \text{there is } R \in \mathbb{R}^{(m-r) \times m}, \text{ such that } R \mathcal{S}(\hat{p}) = 0 \text{ and } R \text{ has full row rank}, \quad (\text{KER})$$

the following equivalent problem to (SLRA) is obtained

$$\begin{align*}
\text{minimize} & \quad \text{over } \hat{p} \in \mathbb{R}^{n_r} \text{ and } R \in \mathbb{R}^{(m-r) \times m} \| p_\mathcal{I} - \hat{p}_\mathcal{I} \|^2_2 \\
\text{subject to} & \quad R \mathcal{S}(\hat{p}) = 0 \text{ and } R \text{ has full row rank}, \quad (\text{SLRA}_R)
\end{align*}$$

Problem (SLRA$_R$) is a double minimization over the parameters $R$ and $\hat{p}$

$$\begin{align*}
\text{minimize} & \quad \text{over } R \in \mathbb{R}^{(m-r) \times m} \quad M(R) \quad \text{subject to } R \text{ has full row rank}, \quad (\text{SLRA}'_R)
\end{align*}$$

where

$$M(R) := \min_{\hat{p}} \| p_\mathcal{I} - \hat{p}_\mathcal{I} \|^2_2 \quad \text{subject to } R \mathcal{S}(\hat{p}) = 0. \quad (\text{INNER})$$

The evaluation of the cost function $M$, i.e., solving (INNER) for a given value of $R$, is referred to as the inner minimization problem. This problem is solved analytically in Section 2. The remaining problem of minimizing $M$ over $R$ is referred to as the outer minimization problem. It is a nonlinear least-squares problem, which, in general, admits no analytic solution. General purpose local optimization methods are used in Section 3 for its numerical solution. In Section 4, the approach is generalized to weighted 2-norm approximation criteria with missing values. Numerical examples of solving approximation problems with missing data by the proposed methods are shown in Section 5.
1.2 Applications

1.2.1 Linear static modeling with missing data: An approximate low-rank matrix completion problem

Consider a set of vectors \( D = \{ d_1, \ldots, d_N \} \) in \( \mathbb{R}^q \). A linear model \( \mathcal{B} \) for the data \( D \) is a subspace of the data space \( \mathbb{R}^q \), and the dimension of \( \mathcal{B} \) is a measure of the model’s complexity. Linear static modeling is the problem of finding a low-complexity model (low-dimensional subspaces) that fits the data as close as possible. Existence of an exact linear model \( \mathcal{B} \) for the data \( D \), i.e., \( D \subseteq \mathcal{B} \), with complexity at most \( r \) is equivalent to the data matrix \( D = [d_1 \cdots d_N] \) having rank at most \( r \). Therefore, measuring the fit between the data point \( d_i \) and the model \( \mathcal{B} \) by the orthogonal distance

\[
\text{dist}(d_i, \mathcal{B}) = \min_{\hat{d}_i \in \mathcal{B}} \| d_i - \hat{d}_i \|_2,
\]

the approximate fitting problem becomes a rank \( r \) matrix approximation problem (SLRA) with unstructured data matrix \( \mathcal{X}(p) = D \).

Suppose now that some elements \( d_{ij}, (i, j) \in \mathcal{I}_{\text{missing}} \) of the data matrix are missing. Equivalently, only the elements \( d_{ij}, (i, j) \in \mathcal{I}_{\text{given}} \) of \( D \) are specified. The exact linear static modeling problem becomes a low-rank matrix completion problem [6]:

\[
\text{find } \hat{D} \text{ such that } \text{rank}(\hat{D}) \leq r \text{ and } \hat{D}_{\mathcal{I}_{\text{given}}} = D_{\mathcal{I}_{\text{given}}}.
\]

Here \( D_{\mathcal{I}} \) denotes the vector of elements of \( D \) with indices in \( \mathcal{I} \). In the context of approximate data fitting by linear static model and missing data values, the relevant problem is approximate low-rank matrix completion [5]:

\[
\text{minimize over } \hat{D} \quad \| \hat{D}_{\mathcal{I}_{\text{given}}} - D_{\mathcal{I}_{\text{given}}} \|_2^2 \text{ subject to } \text{rank}(\hat{D}) \leq r. \quad \text{(AMC)}
\]

The approximate low-rank matrix completion problem (AMC) is used for building recommender systems. In recommender system applications, there is a set of users and a set of products. Some users rate some products. The goal is to predict the user ratings on products that they have not rated. The underlying assumption that makes the solution of this problem possible is that the full user-ratings matrix is low-rank. The low-rank property is observed empirically and can be explained intuitively as existence of a small number of groups of users with the same “taste” (i.e., users that like or dislike the same products). In practice, the low-rank assumption is satisfied only approximately, which makes the approximation aspect of the problem essential.

The main issue in building real-life recommender systems is the high dimensionality and sparsity of the data matrix. Additional important issues in building practical recommender systems is the fact that the given and missing ratings are discrete and that apart from the users’ ratings, there is demographic information about the users. Taking into account this prior information may improve significantly the accuracy of the missing values estimation. These issues, however, are outside the scope of the present paper.

1.2.2 System identification with missing data: An approximate block-Hankel structured low-rank matrix completion problem

A discrete-time linear time-invariant dynamical model is a set of time series

\[
\mathcal{B}(R) := \{ w \mid R_0 w(t) + R_1 w(t+1) + \cdots + R_T w(t+T) = 0, \text{ for all } t \} \quad \text{(B)}
\]

that satisfy a constant coefficients difference equation. The matrices \( R_0, R_1, \ldots, R_T \in \mathbb{R}^{p \times q} \) are parameters specifying the model. Note that the linear static model is a special case of a linear time-invariant dynamical model when the lag \( \ell \) of the difference equation representing the system is equal to zero.

A finite time series

\[ w = (w(1), \ldots, w(T)), \quad \text{where } w(t) \in \mathbb{R}^q, \]

that satisfy a constant coefficients difference equation. The matrices \( R_0, R_1, \ldots, R_T \in \mathbb{R}^{p \times q} \) are parameters specifying the model. Note that the linear static model is a special case of a linear time-invariant dynamical model when the lag \( \ell \) of the difference equation representing the system is equal to zero.
is an exact trajectory of the system defined in (\(\mathcal{B}\)) if the following matrix equation is satisfied

\[
\begin{bmatrix}
R_0 & R_1 & \cdots & R_{\ell}
\end{bmatrix}
\begin{bmatrix}
w(1) & w(2) & w(3) & \cdots & w(T-\ell) \\
w(2) & w(3) & \ddots & & w(T-\ell+1) \\
w(3) & \ddots & & & \vdots \\
\vdots & & & & \vdots \\
w(\ell+1) & w(\ell+2) & \cdots & w(T)
\end{bmatrix}
= 0.
\]

Without loss of generality, we assume that the parameter matrix \(R\) has full row rank \(p\), which implies that

\[\text{rank}(\mathcal{H}_{\ell+1}(w)) \leq q(\ell+1) - p.\]

We showed above that the data \(w\) is an exact trajectory of a system \(\mathcal{B}(R)\), if the block-Hankel matrix \(\mathcal{H}_{\ell+1}(w)\) is rank deficient. Therefore, as in the static case, approximate modeling by a linear time-invariant system is a low-rank approximation problem

\[
\text{minimize over } \hat{w} \|w - \hat{w}\|_2^2 \quad \text{subject to } \text{rank}(\mathcal{H}_{\ell+1}(\hat{w})) \leq q(\ell+1) - p. \quad \text{(SYSID)}
\]

Note, however, that the linear time-invariant model class imposes a block-Hankel structure constraint on the approximation matrix.

Identification from a trajectory with missing elements is therefore a block-Hankel structured low-rank matrix completion problem. A special system identification problems for the class of auto-regressive exogenous systems with missing data is considered in [10] and a method based on frequency domain techniques is proposed in [24]. These papers do not link the system identification problem to the block-Hankel low-rank approximation problem (SYSID), so that their approaches are different from ours. The method developed in this paper, when specialized to block-Hankel structure can be used for general multivariable system identification in the time domain.

1.2.3 Data-driven simulation and control

The trajectory \(w\) of a dynamical system can be partitioned into inputs \(u\), i.e., free variables, and outputs \(y\), i.e., variables that are determined by the inputs, initial conditions, and the model. Let \(w = (u,y)\) be such a partition. The output \(y = (y(1),\ldots,y(T))\) of \(\mathcal{B}\) is uniquely determined by the input \(u = (u(1),\ldots,u(T))\) and the initial conditions

\[w_p = (w(-\ell+1),w(-\ell+2),\ldots,w(0)).\]

This gives a “signal processor” interpretation of a dynamical system.

The simulation problem aims to find the output \(y_t\) of a system \(\mathcal{B}\), corresponding to a given input \(u_t\) and initial conditions \(w_p\), i.e.,

\[
\text{find } y_t \text{ such that } w_p \wedge (u_t,y_t) \in \mathcal{B}.
\]

\((w_p \wedge w_t)\) denotes the concatenation of \(w_p\) and \(w_t\). This is a classic problem in system theory and numerical linear algebra, for which many solutions exist, e.g., for systems with no inputs, the problem is related to the computation of the matrix exponential [22]. The classical simulation methods require a representation (state space, transfer function, convolution kernel, etc.) of the model. Such a representation is often obtained from data by system identification. The
question occurs of solving the simulation problem directly from the data without identifying a model representation as a byproduct and using it in a model based solution. We call the direct problem data-driven simulation [15].

The data-driven simulation problem is a mosaic-Hankel structured low-rank approximation problem with fixed (exact) and missing data. To see this, let \( w' \) denotes the data that implicitly specifies the model and \( w'' = w''_p \land (u''_f, y''_p) \) be the to-be-simulated trajectory. We express the condition that \( w' \) and \( w'' \) are trajectories of a linear time-invariant system with lag \( \ell \) in matrix language as

\[
\text{rank}(\begin{bmatrix} \mathcal{H}_{\ell+1}(w') & \mathcal{H}_{\ell+1}(w'') \end{bmatrix}) \leq q(\ell + 1) - p.
\]

This is a model-free description of the simulation problem—the existence of a model is implicit in the rank constraint. The fixed data are the initial conditions \( w''_p \) and the input \( u''_f \) and the missing data are the to-be computed response \( y''_p \).

When the data \( w' \) is not an exact trajectory of the model, the matrix \( \mathcal{H}_{\ell+1}(w') \) is generically full rank, so that an approximation is needed. The resulting data-driven simulation problem is a mosaic-Hankel structured low-rank approximation with missing data:

\[
\begin{align*}
\text{minimize} & \quad \|w' - \hat{w}'\|^2_2 \\
\text{subject to} & \quad \text{rank}(\begin{bmatrix} \mathcal{H}_{\ell+1}(\hat{w}') & \mathcal{H}_{\ell+1}(\hat{w}'') \end{bmatrix}) \leq q(\ell - 1) - p, \\
& \quad \hat{w}'_p = w_p', \quad \text{and} \quad \hat{u}'_f = u''_f.
\end{align*}
\]

(DDSIM)

Notation

In the rest of the paper, we use the following notation.

- \( A_{I,J} \) is the submatrix of \( A \) with rows in \( I \) and columns in \( J \). The row/column index can be replaced by the symbol \( \cdot \), in which case all rows/columns are selected.

- \( M / G \) is the vector of indices of \( p \) that are missing / given, and \( n_m / n_g \) is the number of missing / given elements.

- \( A^\perp \) is the pseudo inverse of \( A \) and \( A^\perp \) is a matrix which rows form a basis for the left null space of \( A \).
• \text{vec}(\cdot) is the column-wise vectorization operator.

## 2 Analytical solution of the inner minimization problem

In this section, we consider the inner minimization problem (INNER).

**Problem 1.** Given affine structure $\mathcal{S}$, structure parameter vector $p \in \{\mathbb{R} \cup \{\text{NaN}\}\}^{n_p}$, and a kernel parameter $R \in \mathbb{R}^{(m-r) \times m}$, evaluate the cost function $M(R)$, defined in (INNER), and find a point $\hat{p}$ that attains the minimum.

For a given structure $\mathcal{S}$ and $R \in \mathbb{R}^{(m-r) \times m}$, we define the matrix

$$G := \begin{bmatrix} \text{vec}(RS_1) & \cdots & \text{vec}(RS_{n_p}) \end{bmatrix} \in \mathbb{R}^{(m-r) \times n_p}. \quad (G)$$

**Theorem 2.** Under the following assumptions:

1. $G_{gh}$ is full column rank,
2. $1 \leq (m-r)n - n_m \leq n_g$, and
3. $\bar{G} := G_{gh}^\top G_{gh}$ is full row rank,

Problem 1 has a unique global minimum

$$\hat{p}_{gh} = p_{gh} - \bar{G}^\top (\bar{G}\bar{G}^\top)^{-1}s \quad \text{and} \quad \bar{p}_{gh} = -G_{gh}^\top (\text{vec}(RS_0) + G_{gh}\hat{p}_{gh}),$$

with objective function value

$$M(R) = s^\top (\bar{G}\bar{G}^\top)^{-1}s, \quad \text{where} \quad s := \bar{G}p_{gh} + G_{gh}^\top \text{vec}(RS_0). \quad (M)$$

**Proof.** Defining

$$\Delta p_{gh} := p_{gh} - \hat{p}_{gh},$$

and using the identity

$$R\mathcal{S}(\hat{p}) = 0 \iff G\hat{p} = -\text{vec}(RS_0),$$

we have

$$R\mathcal{S}(\hat{p}) = 0 \iff \begin{bmatrix} G_{gh} & G_{gh} \end{bmatrix} \begin{bmatrix} p_{gh} - \Delta p_{gh} \\ \hat{p}_{gh} \end{bmatrix} = -\text{vec}(RS_0).$$

Therefore, (INNER) is equivalent to

$$M(R) := \min_{\Delta p_{gh} \in \mathbb{R}^n, \hat{p}_{gh} \in \mathbb{R}^m} \|\Delta p_{gh}\|_2^2 \quad \text{subject to} \quad \begin{bmatrix} G_{gh} & G_{gh} \end{bmatrix} \begin{bmatrix} \Delta p_{gh} \\ \hat{p}_{gh} \end{bmatrix} = G_{gh}p_{gh} + \text{vec}(RS_0),$$

which is a generalized linear least norm problem. The solution follows from Lemma 4.
\textit{Mslra_ext} \(7\) \equiv

\begin{verbatim}
function \([M, \phi] = \text{Mslra\_ext}(R, \text{tts, p, w, bfs, phi, s0})
p = p(:);
\langle S \mapsto (m,n,p) 24a\rangle
\langle default \phi 25\rangle
\langle default s0 2\rangle
if ~exist('bfs') | isempty(bfs), \langle S \mapsto S 24b\rangle, end
\langle define \ M \ and \ G 5e\rangle
\langle preprocessing \ for \ weighted \ problem 13b\rangle
\langle define \ G 6a\rangle
\langle define \ \bar{G} 6b\rangle
\langle compute \ M \ and \ \hat{p} 6c\rangle
\langle postprocessing \ for \ weighted \ problem 13c\rangle
\end{verbatim}

\textbf{Note 3.} In the case of unstructured matrix, condition 2 of Theorem 2 reduces to \(n_m < (m-r)n\).

\textbf{Generalized least norm problem}

\textbf{Lemma 4.} Consider the generalized linear least norm problem

\[
\begin{align*}
f &= \min_{x,y} \|x\|_2^2 \quad \text{subject to} \quad Ax + By = c, \\
\end{align*}
\]

(GLN)

with \(A \in \mathbb{R}^{m \times n_x}, \ B \in \mathbb{R}^{m \times n_y}, \ \text{and} \ c \in \mathbb{R}^m\). Under the following assumptions:

1. \(B\) is full column rank,
2. \(1 \leq m - n_y \leq n_x\), and
3. \(\bar{A} := B^\perp A\) is full row rank.

problem (GLN) has a unique solution

\[
\begin{align*}
f &= c^T (B^\perp)^T (\bar{A}A^T)^{-1} B^\perp c, \\
x &= \bar{A}^T (\bar{A}A^T)^{-1} B^\perp c \quad \text{and} \quad y = B^+ (c - Ax). \\
\end{align*}
\]

(SOL)

\textbf{Proof.} Under assumption 1, \(B\) has a nontrivial left kernel of dimension \(m - n_y\). Therefore for the nonsingular matrix

\[
T = \begin{bmatrix} B^+ \\ B^\perp \end{bmatrix} \in \mathbb{R}^{m \times m}
\]

\[
TB = \begin{bmatrix} B^+ \\ B^\perp \end{bmatrix} B = \begin{bmatrix} B^+ B \\ B^\perp B \end{bmatrix} = \begin{bmatrix} I_{n_y} \\ 0 \end{bmatrix}.
\]

Pre-multiplying both sides of the constraint of (GLN) by \(T\), we have the following equivalent constraint

\[
\begin{bmatrix} B^+ Ax \\ B^\perp Ax \end{bmatrix} + \begin{bmatrix} y \\ 0 \end{bmatrix} = \begin{bmatrix} B^+ c \\ B^\perp c \end{bmatrix}.
\]

The first equation

\[
y = B^+ (c - Ax)
\]

uniquely determines \(y\), given \(x\). The second equation

\[
B^\perp Ax = B^\perp c
\]

defines a linear constraint for \(x\) only. By assumption 2, it is an underdetermined system of linear equations. Therefore, (GLN) is equivalent to the following standard least norm problem

\[
\begin{align*}
f &= \min_x \|x\|_2^2 \quad \text{subject to} \quad B^\perp Ax = B^\perp c. \\
\end{align*}
\]

(GLN')

By assumption 3 the solution is unique and is given by (SOL). \(\square\)
Note 5 (About assumptions 1–3). Assumption 1 is a necessary condition for uniqueness of the solution. Relaxing assumption 1 implies that any vector in the affine space
\[ Y = B^+(c - Ax) + \text{null}(B) \]
is a solution to (GLN). Assumption 2 ensures that the problem is a least norm problem and has a nontrivial solution. In the case \( m = n_y \), the problem has a trivial solution \( f = 0 \). In the case \( m - n_y > n_x \), the problem generically has no solution because the constraint \((\ast)\) is an overdetermined system of equations. Assumption 3 is also required for uniqueness of the solution. It can also be relaxed, making \( y \) nonunique.

Note 6 (Link to weighted least norm problems with singular weight matrix). Consider the weighted least norm problem
\[
\min_{\bar{z}} \bar{z}^\top W \bar{z} \quad \text{subject to} \quad \bar{D} \bar{z} = c,
\]
with singular positive semidefinite weight matrix \( W \). Using a change of variables \( \bar{z} = T^{-1} z \), where \( T \) is a nonsingular matrix, we obtain the equivalent problem
\[
\min_{\bar{z}} \bar{z}^\top T^\top W T \bar{z} \quad \text{subject to} \quad D T \bar{z} = c.
\]
There exists a nonsingular matrix \( T \), such that
\[ T^\top W T = \begin{bmatrix} I_{n_x} & 0 \\ 0 & 0 \end{bmatrix}. \]
Partitioning \( \bar{z} \) and \( \bar{D} := D T^{-1} \) conformably as
\[ \bar{z} = \begin{bmatrix} x \\ y \end{bmatrix} \quad \text{and} \quad \bar{D} = \begin{bmatrix} A & B \end{bmatrix} \]
we obtain problem (GLN).

3 Outer minimization problem

The outer minimization problem \((\text{SLRA}_R)\) is a nonlinear least-squares problem, which we solve by general purpose local optimization methods. In order to apply standard optimization methods, however, we need first to replace the rank constraint with equivalent equality or inequality constraints.

The kernel parameter \( R \) is constrained to have a specified structure
\[ R : \mathbb{R}^{n_\theta} \to \mathbb{R}^{(m-r) \times m}, \]
i.e., \( R = \hat{R}(\theta) \), for some \( \theta \in \mathbb{R}^{n_\theta} \). An example of a kernel structure \( \hat{R} \) is an affine function
\[ R = \hat{R}(\theta) := \text{vec}^{-1}_{m-r}(\theta \Psi) + R_0, \quad (\theta \mapsto R) \]
defined by matrices \( \Psi \in \mathbb{R}^{n_\theta \times (m-r) m} \) and \( R_0 \in \mathbb{R}^{(m-r) \times m} \).

8a \[ \langle \text{default th2R} 8a \rangle \equiv \]
if ~isfield(opt, ’R0’), opt.R0 = 0; end
if ~exist(‘th2R’) || isempty(th2R)
    th2R = @(th) reshape(th * psi + opt.R0(:,’), m - r, m);
end

8b \[ \langle \text{default psi} 8b \rangle \equiv \]
if ~exist(’psi’, ’var’) || isempty(psi), psi = eye(m * (m - r)); end
The full row rank constraint on $R$ is equivalent to and can be enforced in the parameter optimization method by the equality constraint

$$RR^\top = I_{m-r}. \quad \text{(f.r.r. $R$)}$$

$$\mathcal{C}(\theta) := R(\theta)R^\top(\theta) - I_{m-r} = 0. \quad \text{(11b)}$$

(11a)  

\begin{verbatim}
if ~exist('C') || isempty(C), C = @(th) th2R(th) * th2R(th)' - eye(m - r); end

end
\end{verbatim}

Then, the outer minimization problem becomes a constrained nonlinear least squares problems

$$\begin{align*}
\text{minimize}_{R \in \mathbb{R}^{(m-r)\times m}} & \quad M(R) \quad \text{subject to} \quad RR^\top - I_{m-r} = 0. \\
\end{align*} \quad \text{(SLRA}'_R)$$

(SLRA)'_R is an optimization problem on a Stiefel manifold [1] and can be solved by specialized methods, e.g., the GenRTR package [2], or by general purpose penalty methods for constrained optimization [23]. Next, we consider a penalty method, i.e., reformulation of (SLRA)'_R as a regularized unconstrained nonlinear least squares problem by adding the regularization term $\gamma \|RR^\top - I_{m-r}\|_F^2$, where $\| \cdot \|_F$ is the Frobenius norm, to the cost function

$$\begin{align*}
\text{minimize}_{R \in \mathbb{R}^{(m-r)\times m}} & \quad M(R) + \gamma \|RR^\top - I_{m-r}\|_F^2. \\
\end{align*} \quad \text{(SLRA}''_R)$$

The parameter $\gamma$ should be chosen “large enough” in order to enforce the constraint (f.r.r. $R$). A corollary of the following theorem shows that $\gamma = \|p_{\perp}\|_F^2$ is sufficiently large for linear structures.

\begin{verbatim}
if ~exist('opt') || ~isfield(opt, 'g') || isempty(opt.g)
    opt.g = norm(p(Ig)) ^ 2;
end
\end{verbatim}

\textbf{Theorem 7.} Let $M : \mathbb{R}^{(m-r)\times m} \rightarrow \mathbb{R}_+$ be a homogeneous function, i.e., $M(R) = M(TR)$, for any $R$ and a nonsingular $m \times m$ matrix $T$. Assume that $\gamma$ satisfies

$$\gamma > \min_{\{R \mid \text{rank}(R) = m-r\}} M(R). \quad \text{(11a)}$$

Then, the optimal solutions of problem (SLRA}''_R) coincide with the optimal solutions of (SLRA)'_R).

\textbf{Proof.} We call a set $\mathcal{R} \subset \mathbb{R}^{d\times m}$ a “homogeneous set” if for all $R \in \mathcal{R}$ and for all nonsingular matrices $T \in \mathbb{R}^{d\times d}$, $TR \in \mathcal{R}$. Let $R$ be a solution to (SLRA)'_R with the constraint $R \in \mathcal{R}$, where $\mathcal{R}$ is a homogeneous set. We will show that

$$\|RR^\top - I_{m-r}\|_F^2 = m - r - \text{rank}(R). \quad \text{(11b)}$$

There exists an orthogonal matrix $U$ diagonalizing $RR^\top$. We have,

$$\begin{align*}
\|RR^\top - I_{m-r}\|_F^2 &= \|URR^\top U^\top - I_{m-r}\|_F^2 \\
&= \|\text{diag}(a_1, \ldots, a_{\text{rank}(R)}, 0, \ldots, 0) - I_{m-r}\|_F^2, \quad \text{where } a_i > 0 \\
&= \sum_{i=1}^{\text{rank}(R)} (a_i - 1)^2 + m - r - \text{rank}(R).
\end{align*}$$

Suppose that $a_i \neq 0$ for some $i$. The matrix

$$R' = \text{diag}(1, \ldots, 1, 1/\sqrt{a_i}, 1, \ldots, 1)R$$

has the same row span and rank as $R$, so that by the homogeneity property of $M$, $M(R) = M(R')$. However, we have

$$\|RR^\top - I_{m-r}\|_F^2 > \|R'R^\top - I_{m-r}\|_F^2,$$

so that $R' \in \mathcal{R}$ achieves smaller value of the cost function of (SLRA}'_R) than $R$. This is a contradiction. Therefore, $a_i = 1$ for all $i$. This concludes the proof of (11b).
So far we showed that minimization of the cost function in (SLRA″) on homogeneous sets is equivalent to minimization of

\[ M(R) + \gamma (m - r - \text{rank}(R)). \]  

(M″)

The set of full row rank matrices

\[ \mathcal{R}_f := \{ R \in \mathbb{R}^{(m-r)\times m} \mid \text{rank}(R) = m - r \} \]

and the set of rank-deficient matrices

\[ \mathcal{R}_d := \{ R \in \mathbb{R}^{(m-r)\times m} \mid \text{rank}(R) < m - r \} \]

are homogeneous. Denote the solutions of (SLRA″) on these sets as

\[ M^*_f := \inf_{R \in \mathcal{R}_f} M(R) + \gamma \|RR^\top - I_{m-r}\|_F^2 \]

\[ \geq \gamma \]

\[ M^*_d := \inf_{R \in \mathcal{R}_d} M(R) + \gamma \|RR^\top - I_{m-r}\|_F^2 \]

\[ \geq \gamma \]

\[ \geq \gamma \]

\[ \geq \gamma \]

\[ \geq \gamma \]

Then, \( M^*_f < \gamma \leq M^*_d \) and

\[ M^* := \inf_{R \in \mathbb{R}^{(m-r)\times m}} M(R) + \gamma \|RR^\top - I_{m-r}\|_F^2 = M^*_f. \]

In addition, the minimum of (SLRA″) coincides with \( M^*_f \) by the homogeneity of \( M \). Therefore, the solutions of (SLRA″) and (SLRA′) coincide if one of them exists.

Note 8 (Choice of \( \gamma \)). \( \gamma = \max_{R \in \mathcal{R}} M(R) \) always satisfies condition (\( \gamma \)). In particular, for a linear structure \( \mathcal{S} \), it is sufficient to take \( \gamma = \|p\|_2^2 \), because \( \mathcal{S}(0) \) has zero rank, and \( R \mathcal{S}(0) = 0 \) holds for any \( R \).

\[ \theta_\text{ini} := \text{vec}^\top (\mathcal{R}_\text{ini} - \mathcal{R}_0)\Psi^{-1}. \]
In the case of rectangular $\Psi$ matrix, the mapping $R_{ini} \mapsto \theta_{ini}$ may require approximation. One possible approximation criterion is

$$\minimize_{\theta_{ini}} \| \text{vec}^T (R_{ini} - R_0) - \theta_{ini} \Psi \|$$

which leads to a linear least-squares problem. In the case of nonlinear structure the problem is a nonlinear least-squares minimization

$$\minimize_{\theta_{ini}} \| R_{ini} - \mathcal{A}(\theta_{ini}) \|_F.$$ 

Another way of measuring closeness in the linear case is described next. Let $\hat{D}_{ini}$ be the best unstructured approximation of the data matrix, with image equal to $\ker(R_{ini})$.

$$\langle (R, D) \mapsto \hat{D} \rangle \equiv$$

$$P = \text{null}(R); \ dh = P \ast (P \setminus d);$$

Since, $R_{ini}\hat{D}_{ini} = 0$, the closeness between $R_{ini}$ and $\mathcal{A}(\theta_{ini})$ can be measured by the Frobenius norm of the residual $\mathcal{A}(\theta_{ini})\hat{D}_{ini}$. Imposing the normalization constraint $\|\theta_{ini}\| = 1$, the resulting approximation problem is

$$\minimize_{\theta_{ini}} \| \mathcal{A}(\theta)\hat{D}_{ini} \|_F \ \text{subject to} \ \|\theta\| = 1,$$

which is equivalent to unstructured approximation of the matrix $\Psi(\hat{D}_{ini} \otimes I_{m-r})$ by a rank $n_\theta - 1$ matrix.

$$\langle \text{define } R2th \langle 12b \rangle \rangle \equiv$$

$$\text{function } \text{th} = R2th(R, d, psi, R0)$$

$$\text{if } \text{size(psi, 1) == size(psi, 2)} \& \& \text{all(all(R0 == 0))}$$

$$\langle (R, D) \mapsto \hat{D} \rangle \equiv$$

$$\text{th} = \text{lra(psi * kron(dh, eye(size(R, 1))), size(psi, 1) - 1);}$$

$$\text{else}$$

$$\text{th} = \text{vec}(R - R0)' / psi;$$

$$\text{end}$$

Note 10 (Efficient software implementation). Efficient methods for evaluation of the cost function and its derivatives in the special case of mosaic-Hankel matrix structure is presented in a companion paper [26]. The method, presented in this paper (general affine structure) and the efficient methods of [26] are implemented in Matlab (using Optimization Toolbox) and in C++ (using the Levenberg-Marquardt algorithm [20] from the GNU Scientific Library [7]), respectively. Description of the software and overview of its applications is given in [16].

### 4 Weighted approximation

Problem (SLRA) is generalized in this section to the weighted structured low-rank approximation problem

$$\minimize_{\hat{p}} \in \mathbb{R}^n_p \quad (p_{gq} - \hat{p}_{gq})^T W_g (p_{gq} - \hat{p}_{gq}) \quad \text{subject to} \ \text{rank}(\mathcal{S}(\hat{p})) \leq r,$$

(WSLRA)

where $W_g$ is a positive definite matrix.

In case of a diagonal matrix

$$W_g = \text{diag}(w_g) = \text{diag}(w_1, \ldots, w_{n_g}),$$

the weights can be specified by a positive vector $w_g$.

$$\langle w \mapsto W \langle 12c \rangle \rangle \equiv$$

$$\text{if any(size(w) == 1), } w = \text{diag(w);} \ \text{end}$$

In case of missing data, $w_g$ is $n_g$ dimensional and its indices do not correspond to the indices of the structure parameter vector $p$. Then, it is convenient to specify the weights as $n_p$ vector (or $n_p \times n_p$ matrix) with weights corresponding to the missing elements set as zeros.

$$\langle n_p \times n_p \text{ dimensional } W \mapsto n_g \times n_g \text{ dimensional } W \langle 12d \rangle \rangle \equiv$$

$$\text{if size(w, 1) == np, } w = w(1g, 1g); \ \text{end}$$
The change of variables
\[ p'_{i\ell} = W_g^{1/2} \hat{p}_{i\ell} \quad \text{and} \quad \hat{p}'_{i\ell} = W_g^{1/2} \hat{p}_{i\ell} \] 
reduces Problem (WSLRA) to an equivalent unweighted problem (SLRA). We have
\[ \mathcal{J}(\hat{p}) = S_0 + \text{vec}^{-1}(S\hat{p}), \quad \text{where} \quad S := [\text{vec}(S_1) \cdots \text{vec}(S_{np})] \in \mathbb{R}^{mn \times np}. \] 
\[ (S, \hat{p}) \mapsto \hat{D} = \mathcal{J}(\hat{p}) \]
\[ \text{dh} = \phi \ast \text{reshape(bfs} \ast \phi, \text{mp, n}); \]
The structure \( \mathcal{J}' \) of the equivalent problem is defined by the matrices \( S_0 \) and
\[ S' = [\text{vec}(S'_1) \cdots \text{vec}(S'_n)]', \quad \text{where} \quad S'_{i\ell} = S_{i\ell}\hat{p}_i^{-1/2} \text{and} \quad S'_\# = S_\#. \] 
\[ (\mathcal{J} \mapsto \mathcal{J}') \]
We showed that problem (WSLRA) is solved by:
1. preprocessing the data \( p \) and the structure \( \mathcal{J} \), as in \( (p \mapsto p') \) and \( (\mathcal{J} \mapsto \mathcal{J}') \),
2. solving the equivalent unweighted problem with structure parameter vector \( p' \), structure specification \( \mathcal{J}' \), and rank specification \( r \), and
3. postprocessing the solution \( \hat{p}' \), obtained in step 2, in order to obtain the solution \( \hat{p}_i = W_g^{-1/2} \hat{p}'_i \) of the original problem.
\[ \text{dh} = \phi \ast \text{reshape(bfs} \ast \phi, \text{mp, n}); \]
\[ \text{sqrt}_w = \text{sqrtm}(w); \quad \text{inv_sqrt}_w = \text{pinv}(	ext{sqrt}_w); \]
\[ \text{sqrt}_w = \text{sqrtm}(w); \quad \text{inv_sqrt}_w = \text{pinv}(	ext{sqrt}_w); \]
\[ \text{bfs}(:, Ig) = \text{bfs}(:, Ig) \ast \text{inv_sqrt}_w; \]
Using the transformation \( (p \mapsto p') \), \( (\mathcal{J} \mapsto \mathcal{J}') \) and the solution \( (M) \) of (SLRA), we obtain the following explicit expression for the cost function of (WSLRA)
\[ M(R) = (\tilde{G}p_{\ell} - G_{\#;\ell}^\perp \text{vec}(RS_0))^\top W_g^{-1} \tilde{G}^\top (\tilde{G}W_g^{-1} \tilde{G}^\top)^{-1} \tilde{G}W_g^{-1} (\tilde{G}p_{\ell} - G_{\#;\ell}^\perp \text{vec}(RS_0)), \] 
\[ (M_W) \]
where \( \tilde{G} = G_{\#;\ell}^\perp G_{\#;\ell} \) and \( G \) is defined in (G).
\[ \text{Note 11} \ (\text{Specification of fixed parameter values by infinite weights}). \quad \text{In the case of a diagonal weight matrix (}w_g\text{), an infinite weight} \ w_{ij} = \infty \ \text{specifies a fixed parameter value} \ \hat{p}_j = p_j. \ \text{A problem with infinite weights is equivalent} \ \text{to a regular structured low-rank approximation problem with fixed parameters assigned to the constant term} \ S_0 \ \text{of the structure specification. Let} \ \mathcal{J}_f \ \text{be the set of indices of the fixed structure parameters and} \ \mathcal{J}'_f \ \text{its complement} \]
\[ \mathcal{J}_f = \{ j \in \{1, \ldots, n_p \} \mid \hat{p}_j = p_j \} \quad \text{and} \quad \mathcal{J}'_f = \{ j \in \{1, \ldots, n_p \} \mid j \notin \mathcal{J}_f \}. \]
The equivalent problem has structure, defined by
\[ \mathcal{J}'(\hat{p}') = S_0 + \sum_{i \in \mathcal{J}_f} S_i p_i + \sum_{i \in \mathcal{J}_f} S_i \hat{p}_i, \quad \text{where} \quad \hat{p}' := \hat{p}|_{\mathcal{J}'_f}. \]
If \( = \text{find}(\text{isinf}(	ext{diag}(w))) \);

if ~isempty(If)

\[
\begin{align*}
pf & = p(Ig(If)); \\
s0 & = s0 + \text{reshape}(\text{bfs}(:, Ig(If)) \ast pf, mp, n); \\
w(If, :) & = []; w(:, If) = []; p(Ig(If)) = []; \\
bfs(:, Ig(If)) & = []; \\
Ig_ & = Ig; np_ = np; np = \text{length}(p); \\
tts & = \text{reshape}(\text{bfs} \ast \text{vec}(1:np), mp, n);
\end{align*}
\]

end

The estimated vector \( \hat{p} \) is recovered from the parameter vector \( \hat{p}' \) of the equivalent problem by

\[
\hat{p}|_{\mathcal{H}_1} = \hat{p}' \quad \text{and} \quad \hat{p}|_{\mathcal{G}_1} = p|_{\mathcal{G}_1}.
\]

\[\text{(13b)}\]

Note 12 (Solving (SLRA) as weighted unstructured problem). Consider an instance of problem (SLRA), referred to as problem P1, with structure \( \mathcal{S}_1 = \mathcal{S}_1 \) and an instance of problem (WSLRA), referred to as problem P2, with unstructured correction (\( \mathcal{S}_2 = \text{vec}^{-1}, n_{p_2} = mn \)) and weight matrix \( W_2^{-1} = S_1S_1^\top \).

\[\text{(13c)}\]

It can be verified by inspection that the cost functions (M) and (M_W) of problems P1 and P2, respectively, coincide. The weight matrix \( W_2 \in \mathbb{R}^{mn \times mn} \), defined in (\( \mathcal{H}_1 \mapsto \mathcal{W}_2 \)), however is singular (\( \text{rank}(W_2) \) is equal to the number of structure parameters of problem P1, which is less than \( mn \)). In the derivation of the cost function (M_W) it is assumed that \( W_2 \) is positive definite, so that minimization of (M_W) is not equivalent to problem P2.

5 Numerical examples

In this section, we present numerical examples with the three problems covered in the introduction:

- unstructured noisy matrix completion,
- system identification with missing data, and
- data-driven simulation.

The correctness of the results and the effectiveness of the methods in the paper is validated by comparison with alternative methods, specifically developed for these applications. All simulations are done in Matlab and are reproducible in the sense of [4]. An extended version [17] of this paper is a literate program (in noweb format [25]), implementing the methods in the paper and generating the presented numerical results. The necessary m-files can be downloaded from

http://homepages.vub.ac.be/~imarkovs/publications.html

5.1 Approximate matrix completion

In the approximate matrix completion problem (AMC) of Section 1.2.1, the methods in the paper are compared with the following alternative methods:

wlra — the alternating projections method of [13],

\[ 15a \quad \langle \text{wlra 15a} \rangle \equiv \]
\[ \text{method = 'wlra';} \]
\[ \text{addpath ~/mfiles/missing-data;} \]
\[ [\text{Ph, Lh, info_wlra}] = \text{wlra}(d, r, E); \quad \text{dh = Ph * Lh;} \]

optspace — a method based on spectral techniques and manifold optimization [11],

\[ 15b \quad \langle \text{optspace 15b} \rangle \equiv \]
\[ \text{method = 'optspace';} \]
\[ \text{addpath ~/slra-ext-code/OptSpace_matlab_Reg/;} \]
\[ [X S Y \text{ info_opt}] = \text{OptSpace(sparse(d), r, 100, [], 0, E);} \quad \text{dh = X * S * Y'}; \]

lmafit — the successive over-relaxation algorithm of [27], and

\[ 15c \quad \langle \text{lmafit 15c} \rangle \equiv \]
\[ \text{method = 'lmafit';} \]
\[ \text{addpath ~/slra-ext-code/LMaFit-adp/;} \]
\[ \text{addpath ~/slra-ext-code/LMaFit-adp/Utilities;} \]
\[ \text{opts = []; \quad \text{opts.maxit = 1000; \quad \text{opts.est_rank = 0;}} \]
\[ \text{opts.rank_min = r; \quad opts.rank_max = r;} \]
\[ \text{[Ik, Jk] = ind2sub([m n], Ig);} \]
\[ \text{data = partXY(eye(m), d, Ik, Jk, length(Ig))}; \]
\[ [X, Y, \text{info_adp}] = \text{lmafit_mc_adp(m, n, r, Ig', data, opts);} \quad \text{dh = X * Y}; \]
rtmc — the Riemannian trust-region method of [3].

16a  \( \text{rtmc} \) \( \equiv \)
\[
\text{method} = \text{'rtmc'};
\text{addpath} ~/\text{slra-ext-code}/;
\text{addpath} ~/\text{slra-ext-code/rtmc};
\text{addpath} ~/\text{slra-ext-code/GenRTR/solvers};
Jrtr = \text{floor}((Ig - 1) ./ m) + 1; Irtr = \text{rem}((Ig - 1), m) + 1;
\text{problem} = \text{buildproblem}(\text{Irtr, Jrtr, d(Ig), ones(size(Ig)), m, n, r, 1e-6);}
\text{U0} = \text{initialguess}(\text{problem});
[U \ W \ \text{stats}] = \text{rtmc}(\text{problem, opts, U0}); dh = \text{reshape}(U * W, m, n);
\]

These methods use an image representation
\[
\hat{D} = \mathcal{S}(\hat{p}) = PL, \quad \text{where} \quad P \in \mathbb{R}^{m \times r} \text{ and } L \in \mathbb{R}^{r \times n},
\]
of the unstructured \( m \times n \) rank \( r \) matrix \( \hat{D} \). The number of optimization variables in the image representation is \( r(m + n) \) \( (rm \text{ in the case of rtmc}) \), so that the methods are suitable for problems with small rank \( r \). The above cited methods are developed for recommender system applications, where the data matrix is sparse in the given elements and this sparsity is effectively used in the computations.

In contrast, the kernel representation (KER) has \( m(m - r) \) variables, so that it is suitable for problems with small co-rank \( m - r \). The implementation [17] of the methods in the paper is applicable for relatively small size problems (say, \( m < n < 100, \text{ and } m - r < 3 \)). For larger problems, the efficient C implementation [16] (denoted by slra-c below), of the variable projection approach without missing values, can be used by setting the missing values to zeros and the corresponding weights to a small number \( (10^{-6} \text{ in the simulation examples}) \). The In the reported results, slra-m corresponds to (SLRA\( _m \)) and slra-r corresponds to (SLRA\( _r \)) with \( \gamma = \|\hat{p}\|_2^2 \) (see Note 8).

16b  \( \text{slra-m} \) \( \equiv \)
\[
\text{method} = \text{'slra-m'}; \quad p = d(:); \quad p(\text{Im}) = \text{NaN};
\text{if} \quad n < 150,
[\text{ph, info_slra_m}] = \text{slra_ext}(\text{tts, p, r, vec(E)}); \quad \text{dh} = \text{reshape(ph, m, n)};
\text{else,} \quad \text{dh} = \text{NaN} * \text{ones(m, n)}; \quad \text{end},
\]

16c  \( \text{slra-r} \) \( \equiv \)
\[
\text{method} = \text{'slra-r'}; \quad \text{opt.method} = \text{'reg'};
\text{if} \quad n < 150,
[\text{ph, info_slra_m_reg}] = \text{slra_ext}(\text{tts, p, r, vec(E), [], [], [], opt}); \quad \text{dh} = \text{reshape(ph, m, n)};
\text{else,} \quad \text{dh} = \text{NaN} * \text{ones(m, n)}; \quad \text{end},
\]

16d  \( \text{slra-c} \) \( \equiv \)
\[
\text{method} = \text{'slra-c'};
\text{s.m} = \text{ones(m, 1)}; \quad \text{s.n} = \text{ones(n, 1)}; \quad \text{s.w} = \text{vec(E)}; \quad \text{opt.maxiter} = 200;
(\text{approximate zero weights by small positive weights 16c})
[\text{ph, info_slra_c}] = \text{slra}(\text{d(:), s, r, opt}); \quad \text{dh} = \text{reshape(ph, m, n)};
\]

16e  \( \langle \text{approximate zero weights by small positive weights 16c} \rangle \)
\[
\text{s.w}(\text{Im}) = 1 \times 10^{-6};
\]

The data matrices, used in the simulation examples, are generated as random rank \( r \) matrices \( \mathcal{S}(\hat{p}) \) plus noise, where the noise matrix is zero mean Gaussian with independent identically distributed elements. A fraction of randomly selected elements of the data matrix are missing. The simulation parameters for the experiments are:

- matrix dimensions and rank, defined by variables \( m, n, \text{ and } r \), respectively;
- noise level, defined by a variable \( nl \), and
• fraction of given elements, defined by a variable eps.

The relative approximation errors
\[
e_g = \frac{\|p_G - \hat{p}_G\|_2}{\|p_G\|_2} \quad \text{and} \quad e_m = \frac{\|\bar{p}_M - \hat{p}_M\|_2}{\|\bar{p}_M\|_2}
\]
(rows eg and em) and execution time (row t) are shown below for the methods compared in three simulation problems. In a problem with exact $10 \times 100$ matrix of rank 8 with 8 missing values (exact matrix completion problem):

\[\langle \text{AMC, example 1} \rangle\]
\[
ex = 'amc-ex1'; m = 10; n = 100; r = 8; nl = 0; eps = 0.995; test_amc
\]
the methods in the paper, wlra, and rtrmc recover exactly the missing values:

<table>
<thead>
<tr>
<th>slra-m</th>
<th>slra-r</th>
<th>slra-c</th>
<th>wlra</th>
<th>optspace</th>
<th>lmafit</th>
<th>rtrmc</th>
</tr>
</thead>
<tbody>
<tr>
<td>eg</td>
<td>2×10^{-16}</td>
<td>2×10^{-16}</td>
<td>1.2410×10^{-4}</td>
<td>5×10^{-11}</td>
<td>0.0213</td>
<td>2.5156×10^{-4}</td>
</tr>
<tr>
<td>em</td>
<td>1×10^{-14}</td>
<td>1×10^{-14}</td>
<td>0.0013</td>
<td>3×10^{-9}</td>
<td>0.9204</td>
<td>0.1923</td>
</tr>
<tr>
<td>time, sec</td>
<td>1.3632</td>
<td>3.5105</td>
<td>0.2710</td>
<td>0.1614</td>
<td>0.2992</td>
<td>0.0440</td>
</tr>
</tbody>
</table>

For the same setup with 10% noise (approximate matrix completion):

\[\langle \text{AMC, example 2} \rangle\]
\[
ex = 'amc-ex2'; m = 10; n = 100; r = 8; nl = 0.1; eps = .995; test_amc
\]
the methods in the paper, wlra, and rtrmc obtain the same approximation error (around 8% for the missing values).

<table>
<thead>
<tr>
<th>slra-m</th>
<th>slra-r</th>
<th>slra-c</th>
<th>wlra</th>
<th>optspace</th>
<th>lmafit</th>
<th>rtrmc</th>
</tr>
</thead>
<tbody>
<tr>
<td>eg</td>
<td>0.0117</td>
<td>0.0117</td>
<td>0.0154</td>
<td>0.0117</td>
<td>0.0231</td>
<td>0.0118</td>
</tr>
<tr>
<td>em</td>
<td>0.0796</td>
<td>0.0797</td>
<td>0.1439</td>
<td>0.0803</td>
<td>0.9376</td>
<td>0.1233</td>
</tr>
<tr>
<td>time, sec</td>
<td>10.0445</td>
<td>36.9907</td>
<td>0.2400</td>
<td>0.0968</td>
<td>0.3364</td>
<td>0.0465</td>
</tr>
</tbody>
</table>

As illustrated by the following example, increasing the number of missing values eventually makes the solution of the exact matrix completion problem nonunique:

\[\langle \text{AMC, example 3} \rangle\]
\[
ex = 'amc-ex3'; m = 10; n = 100; r = 8; nl = 0; eps = 0.8; test_amc
\]

<table>
<thead>
<tr>
<th>slra-m</th>
<th>slra-r</th>
<th>slra-c</th>
<th>wlra</th>
<th>optspace</th>
<th>lmafit</th>
<th>rtrmc</th>
</tr>
</thead>
<tbody>
<tr>
<td>eg</td>
<td>5×10^{-17}</td>
<td>5×10^{-17}</td>
<td>0.0052</td>
<td>0.0086</td>
<td>0.0509</td>
<td>0.0079</td>
</tr>
<tr>
<td>em</td>
<td>0.5374</td>
<td>0.5374</td>
<td>1.1876</td>
<td>9.5087</td>
<td>0.6133</td>
<td>0.7648</td>
</tr>
<tr>
<td>time, sec</td>
<td>0.7271</td>
<td>3.1331</td>
<td>0.2497</td>
<td>0.3473</td>
<td>0.3229</td>
<td>0.1185</td>
</tr>
</tbody>
</table>

Note that, again the methods in the paper and rtrmc find the same solution, which in the example fits the given data exactly.

For a problem with $10 \times 1000$ matrix of rank 9 with 101 missing values and 5% noise

\[\langle \text{AMC, example 4} \rangle\]
\[
ex = 'amc-ex4'; m = 10; n = 1000; r = 9; nl = 0.05; eps = .99; test_amc
\]
slra-m and slra-r are not applicable (they require too much time and memory). However, the C implementation slra-c is competitive with the alternative methods in terms of execution time and obtains the same approximation error as rtrmc. In this example, lmafit achieves the smallest error and is also the fastest of all compared methods.

<table>
<thead>
<tr>
<th>slra-m</th>

</tbody>
</table>

\[\langle \text{evaluate AMC} \rangle\]
\[
i = i + 1; \quad \text{methods}(i) = \text{method};
\]
\[
\text{if isnan}(\text{dh}), \quad t(i) = \text{NaN}; \quad \text{else} \quad t(i) = \text{toc}; \quad \text{end}
\]
\[
eg(i) = \text{norm}(\text{d}(\text{Ig}) - \text{dh}(\text{Ig})) / \text{norm}(\text{d}(\text{Ig}));
\]
\[
em(i) = \text{norm}(\text{d}(\text{Im}) - \text{dh}(\text{Im})) / \text{norm}(\text{d}(\text{Im}));
\]
The data is simulated using the random number generators \texttt{rand} and \texttt{randn}. In order to make the results reproducible, we first initialize the random number generators’ seeds.

An \( m \times n \) random matrix \( D(d0) \) with rank \( r \) is generated as the product of \( m \times r \) and \( r \times n \) factors that have independent uniformly distributed elements in the interval \([0, 1]\).

An \( m \times n \) random matrix \( \bar{D} \) with \( \bar{D} = \frac{\bar{Q}_2}{\bar{P}_2} = [-1 \ 1] \) \((*)\) is generated as the product of \( m \times r \) and \( r \times n \) factors that have independent uniformly distributed elements in the interval \([0, 1]\).

The noisy data matrix is the sum of the true matrix \( \bar{D} \) and random matrix \( \tilde{D} \), whose elements are independent normally distributed with zero mean and variance proportional to \( n \lambda \)

\[
D = \bar{D} + \tilde{D}, \quad \text{where} \quad \text{vec}(\tilde{D}) \sim N(0, n \lambda^2 \text{var}(\bar{P}) I).
\]

The noisy data matrix is the sum of the true matrix \( \bar{D} \) and random matrix \( \tilde{D} \), whose elements are independent normally distributed with zero mean and variance proportional to \( n \lambda \)

\[
D = \bar{D} + \tilde{D}, \quad \text{where} \quad \text{vec}(\tilde{D}) \sim N(0, n \lambda^2 \text{var}(\bar{P}) I).
\]

The location of the missing elements is specified by the zeros of the matrix \( E \) and are randomly chosen.

The approximation methods are applied and the relative errors \( e_m \) and \( e_g \) are computed.

5.2 System identification with missing data

Consider the system identification problem (SYSID), described in Section 1.2.2. The data \( w \) is a noisy \( T = 100 \) samples long random trajectory of a single-input single-output linear time-invariant system \( \mathcal{B}(\bar{R}) \) with lag \( \ell = 2 \). Samples \( w(t) \), for \( t \in T \), are missing. The noise is zero mean white Gaussian process with covariance matrix \( \sigma^2 I_q \), \( i.e., \) both the inputs \( u = w_1 \) and the outputs \( y = w_2 \) are perturbed and the input and the output noise variances are equal.

The true model parameters

\[
\bar{R}_0 = \begin{bmatrix} -1 & 0.81 \end{bmatrix}, \quad \bar{R}_1 = \begin{bmatrix} 1 & -1.456 \end{bmatrix}, \quad \bar{R}_2 = \begin{bmatrix} \bar{Q}_2 & \bar{P}_2 \end{bmatrix} = [-1 \ 1] \quad \text{(*)}
\]

are normalized with \( \tilde{P}_2 = 1 \) and the same normalization is used for the identified model parameter \( \tilde{R} \). This ensures that the parameters are unique and the systems \( \mathcal{B}(\bar{R}) \) and \( \mathcal{B}(\tilde{R}) \) can be compared by the relative parameter error

\[
e_R = \frac{\|\bar{R} - \tilde{R}\|_2}{\|\bar{R}\|_2}.
\]

\[
R0_vec = \text{vec}(\text{shiftdim}(R0, 3)); \quad e = \text{norm}(R0_vec - Rh) / \text{norm}(R0_vec);
\]

\[
R0_vec = \text{vec}(\text{shiftdim}(R0, 3)); \quad e = \text{norm}(R0_vec - Rh) / \text{norm}(R0_vec);
\]
Assuming SISO system:

### 19a
\[ \text{true system} \equiv \begin{align*}
R0(1, :, :) &= [1 0.81]; \\
R0(2, :, :) &= [-1 -1.456]; \\
R0(3, :, :) &= [1 1]; \\
\end{align*} \]

\[ \text{ell1, p, q} = \text{size}(R0); \quad \text{ell} = \text{ell1} - 1; \quad m = q - p; \]

\[ Q0 = -R0(:, :, 1:m); \quad P0 = R0(:, :, m + 1:q); \]

\[ \text{sys0} = \text{tf}(\text{fliplr}(Q0(:)'), \text{fliplr}(P0(:)'), 1); \]

The Control Toolbox [21] of Matlab is used to simulate a response of the model.

### 19b
\[ \text{simulate} \equiv \begin{align*}
u0 &= \text{rand}(T, m); \quad y0 = \text{lsim}(	ext{sys0}, u0); \quad w0 = [u0 \ y0]; \quad w0 = [u0 \ y0]; \]

Note that in the Control Toolbox, the coefficients of the numerator and denominator polynomials are ordered in decreasing degrees, while the parameters in (\(B\)) and the kernel coefficients in (SYSID) are ordered in increasing degrees. This requires interchanging the order when passing parameters to and receiving parameters from the Control Toolbox functions.

### 19c
\[ \text{add noise} \equiv \begin{align*}
w0 &= \text{randn}(T, q); \quad w = w0 + n1 * w0 / \text{norm}(w, 'fro') * \text{norm}([u0 \ y0], 'fro'); \\
\end{align*} \]

The identification problem is solved by the methods \textsl{slra-m} and \textsl{slra-r}, developed in the paper; the efficient software \textsl{slra-c} of [16] (with zero weights substituted by small constants); and the method \textsl{sysid} of [24].

### 19d
\[ \text{missing data} \equiv \begin{align*}
w(Tm, :) &= \text{NaN}; \\
\end{align*} \]

### 19e
\[ \text{slra-m SYSID} \equiv \begin{align*}
[\text{wh}, \text{info}] &= \text{slra_ext}(\text{s2s}(s), \text{w}(:, \text{r}, \text{s.w}); \quad \text{wh} = \text{reshape}(\text{wh}, T, q); \\
\text{Rh} &= \text{info.Rh} / \text{info.Rh}(\text{end}); \\
\end{align*} \]

### 19f
\[ \text{slra-r SYSID} \equiv \begin{align*}
opt.method &= '\text{reg}'; \\
[\text{wh}, \text{info}] &= \text{slra_ext}(\text{s2s}(s), \text{w}(:, \text{r}, \text{s.w}, [], [], [], \text{opt}); \\
\text{wh} &= \text{reshape}(\text{wh}, T, q); \quad \text{Rh} = \text{info.Rh} / \text{info.Rh}(\text{end}); \\
\end{align*} \]

### 19g
\[ \text{slra-c SYSID} \equiv \begin{align*}
\text{Im} &= \text{find}(\text{s.w} == 0); \quad \text{(approximate zero weights by small positive weights 16e), opt.Rini = Rh;} \\
[\text{wh}, \text{info}] &= \text{slra}(\text{w}(:, \text{s}, \text{r}, \text{opt}); \quad \text{wh} = \text{reshape}(\text{wh}, T, q); \\
\text{Rh} &= \text{info.Rh} / \text{info.Rh}(\text{end}); \\
\end{align*} \]

### 19h
\[ \text{misdata} \equiv \begin{align*}
\text{try} \\
\text{w_id} &= \text{misdata}(\text{iddata}(\text{w}(:, 2), \text{w}(:, 1))) \\
\text{sysy} &= \text{oe}([\text{w_id}, \text{ell ell 0}]); \\
\text{yh} &= \text{filter}([\text{sysy.\text{b}}, \text{sysy.\text{f}}, \text{w_id.u}(:, 1))); \\
\text{wh} &= \text{reshape}(\text{w_id.u yh}); \quad \text{[Qh Ph]} = \text{tfdata}(\text{sysy}, 'v'); \\
\text{Rh} &= \text{[- fliplr(Qh) fliplr(Ph)];} \\
\text{catch} \\
\text{wh} &= \text{NaN}; \quad \text{Rh} = \text{NaN}; \\
\text{end} \\
\end{align*} \]

### 19i
\[ \text{nucnrm} \equiv \begin{align*}
\text{addpath ~/mfiles/nucnrm/} \\
\text{ww} &= \text{s.w}; \quad \text{ww(isnan(ww))} = 0; \\
\text{wh} &= \text{slra_mn}(\text{ww}(:, \text{s2s(s), r, [], [], [s.w]);} \\
\text{Rh} &= \text{??}; \quad \text{wh} = \text{reshape}(\text{wh}, T, q); \\
\end{align*} \]

### 19j
\[ \text{sysid} \equiv \begin{align*}
\text{addpath ~/mfiles/missing-data-dynamic/rik/} \\
\text{try} \\
\text{[sysy, wh_m]} &= \text{sysid_missing_data_rik}(\text{w(:, 1), w(:, 2), ell, std(wt}); \\
\text{[Qh Ph]} &= \text{tfdata}(\text{sysy}, 'v'); \\
\text{Rh} &= \text{[- fliplr(Qh) fliplr(Ph)];} \\
\text{catch}, \\
\end{align*} \]
wh_m = NaN; Rh = NaN;
end
wh = zeros(size(w)); wh(Tm, :) = wh_m;

The simulation parameters in the experiments are the

- number of samples \( T \),
- set of missing values \( T_m \), specified by a variable \( T_m \), and
- noise variance interval, specified by a vector \( NL \).

The reported results show the estimation error \( e_R \) for the compared methods and for the different noise levels specified in \( NL \). In the case of uniformly distributed missing data samples:

\[
\begin{array}{cccccccc}
\sigma & 0 & 0.0143 & 0.0286 & 0.0429 & 0.0571 & 0.0714 & 0.0857 & 0.1000 \\
slra-m & 1.5624 \times 10^{-15} & 0.0085 & 0.0134 & 0.0390 & 0.0325 & 0.0693 & 0.0347 & 0.0778 \\
slra-r & 1.5624 \times 10^{-15} & 0.0085 & 0.0134 & 0.0390 & 0.0325 & 0.0693 & 0.0347 & 0.0778 \\
slra-c & 2.9202 \times 10^{-6} & 0.0085 & 0.0134 & 0.0390 & 0.0325 & 0.0693 & 0.0347 & 0.0778 \\
sysid & 5.6315 \times 10^{-15} & 0.0096 & 0.0148 & 0.0434 & 0.0356 & 0.0697 & 0.0322 & 0.0758 \\
\end{array}
\]

Similar results are obtained in the case of consecutive missing samples:

\[
\begin{array}{cccccccc}
\sigma & 0 & 0.0143 & 0.0286 & 0.0429 & 0.0571 & 0.0714 & 0.0857 & 0.1000 \\
slra-m & 1.6123 \times 10^{-15} & 0.0063 & 0.0142 & 0.0366 & 0.0529 & 0.0738 & 0.0410 & 0.0850 \\
slra-r & 1.6123 \times 10^{-15} & 0.0063 & 0.0142 & 0.0366 & 0.0529 & 0.0738 & 0.0411 & 0.0851 \\
slra-c & 6.5227 \times 10^{-7} & 0.0063 & 0.0142 & 0.0366 & 0.0529 & 0.0738 & 0.0411 & 0.0851 \\
sysid & 3.3311 \times 10^{-16} & 0.0080 & 0.0191 & 0.0431 & 0.0578 & 0.0766 & 0.0417 & 0.0829 \\
\end{array}
\]

This latter problem can be solved also by treating the data as two independent trajectories without missing data.

```matlab
% Test sysid 20c
randn('seed', 0); rand('seed', 0); clear e_*
true system 19a, simulate \( \hat{w} \) 19b
structure specification for identification 4a)
for i = 1:N
    nl = NL(i); % add noise 19c, missing data 19d
    (weights for identification with missing values 4b)
    (slra-m SYSID 19e), (evaluate SYSID 18g), e_slra_m(i) = e;
    (slra-r SYSID 19f), (evaluate SYSID 18g), e_slra_r(i) = e;
    (slra-c SYSID 19g), (evaluate SYSID 18g), e_slra_c(i) = e;
    (sysid 19h), (evaluate SYSID 18g), e_sysid(i) = e;
end
labels = {'nl'; 'slra-m'; 'slra-r'; 'slra-c'; 'sysid'};
res = [labels, num2cell([NL; e_slra_m; e_slra_r; e_slra_c; e_sysid])]
eval(['!rm ' ex]), diary(ex), disp(res), pause(.1), diary off
```

20
5.3 Data-driven simulation

Consider the data-driven simulation problem (DDSIM), described in Section 1.2.3. The to-be-simulated system is \( \bar{B} = B(\bar{R}) \), with parameter \( \bar{R} \) given in (\( \ast \)) and with an input/output partition \( w = (u, y) \) of the variables. The given trajectory \( w' = (u', y') \in (\mathbb{R}^2)^T \) is a noise corrupted random trajectory of \( B \) (the same simulation setup as in Section 5.2) and the to-be-simulated trajectory \( w'' = (u'', y'') \in (\mathbb{R}^2)^T \) is the impulse response \( \hat{h} \) of \( B \), i.e., the response of \( \bar{B} \) to pulse input under zero initial conditions:

\[
\begin{align*}
\mathcal{u}' & = (0, \ldots, 0, 1, 0, \ldots, 0) & \mathbf{pulse\ input} \\
\mathcal{y}' & = (0, \ldots, 0, \hat{h}(0), \hat{h}(1), \ldots, \hat{h}(T_2 - \ell - 1)) & \mathbf{impulse\ response}
\end{align*}
\]

The methods in the paper are compared with an alternative subspace-type method \( \text{ddsim} \) [19, 15] in terms of the relative approximation error

\[
e_h = \frac{\| \hat{h} - \hat{h} \|_2}{\| \hat{h} \|_2}.
\]

Subspace methods are multi stage methods, i.e., they split the nonconvex optimization problem in several steps that are individually convex, but do not guarantee global or local optimally with respect to the overall problem. In general, subspace-type methods are more efficient but less accurate than local optimization-based methods. The results for \( T' = 30, T'' = 52, \) and noise level in the range 0–40%:

\[
\begin{array}{lccccc}
\sigma & 0 & 0.0200 & 0.0400 & 0.0600 & 0.0800 & 0.1000 \\
\text{slra-m} & 1.8920 \times 10^{-15} & 0.0451 & 0.1149 & 0.1652 & 0.2678 & 0.2301 \\
\text{slra-r} & 1.8920 \times 10^{-15} & 0.0451 & 0.1150 & 0.1652 & 0.2679 & 0.2298 \\
\text{slra-c} & 1.0123 \times 10^{-5} & 0.0451 & 0.1149 & 0.1652 & 0.2679 & 0.2298 \\
\text{ddsim} & 3.2215 \times 10^{-15} & 0.0572 & 0.1727 & 0.2772 & 0.3012 & 0.5311
\end{array}
\]

The true impulse response and the approximations for the 40% noise run are plotted in Figure 1.
Figure 1: Data-driven simulation of impulse response: true impulse response — solid line, approximation by the methods in the paper — dashed line, approximation by the methods of [15] — dashed-dotted line.

22a \[
\text{test_ddsim 22a} \equiv \\

\text{nl = NL(i);} \\
\text{T = T1; } \text{(simulate w 19b), } \text{(add noise 19c), wl = w;} \\
\text{w' impulse response 21a} \\
\text{slra-m DDSIM 21c} \text{ (evaluation DDSIM 21g), e_slra_m(i) = e; hh1 = hh;} \\
\text{slra-r DDSIM 21d} \text{ (evaluation DDSIM 21g), e_slra_r(i) = e;} \\
\text{slra-c DDSIM 21e} \text{ (evaluation DDSIM 21g), e_slra_c(i) = e;} \\
\text{alternative method for DDSIM 21f}, \text{ (evaluation DDSIM 21g), e_ddsim(i) = e; hh2 = hh;} \\
\text{end} \\
\text{labels = {'nl'; 'slra-m'; 'slra-r'; 'slra-c'; 'ddsim'};} \\
\text{res = [labels, num2cell([NL; e_slra_m; e_slra_r; e_slra_c; e_ddsim])];} \\
\text{eval(['!rm ' ex]), diary('ddsim_ex'), disp(res), pause(.1), diary off} \\
\text{figure} \\
\text{plot(hh1(2:end), 'b'), hold on, plot(h0(2:end), 'r'), plot(hh2(2:end), 'k')} \\
\text{ax = axis; axis([1, T2 - ell - 1, ax(3:4)]), print_fig('slra-ext-f2')}
\]

Compare the result with the one obtained by identification of a model and model based simulation:

22b \[
\text{alternative method: SYSID + simulation 22b} \equiv \\
\text{tts = blkhank(reshape(1:(T1 * q), q, T1), ell + 1);} \\
\text{[whl_, info_] = slra_ext(tts, vec(wl'), q * ell + 1);} \\
\text{syssh_ = tf(fliplr(info_.Rh(1:2:end)), - fliplr(info_.Rh(2:2:end)), -1);} \\
\text{hh_ = impulse(syssh_, T2 - ell1); hh_ = hh_(1:T2 - ell1);} \\
\text{norm(hh - hh_)}
\]

6 Conclusions

A variable-projection-like method for structured low-rank approximation with missing data was developed. The approach was furthermore generalized to weighted structured low-rank approximation with missing values. After elimination of the approximation \( \hat{p} \), the remaining nonlinear least-squares problem subject to quadratic equality constraints was solved as an equivalent regularized unconstrained optimization problem.

The problem and solution methods developed have applications in matrix completion (unstructured problems), system identification with missing data, and data-driven simulation and control (mosaic-Hankel structured problems).
The performance of the methods in the paper was illustrated on small-size simulation examples and was compared with the performance of problem specific methods. Efficient implementation for large scale problems appearing in applications such as recommender systems and system identification is a topic of future research.

Acknowledgements

The implementation of the method \texttt{sysid} for system identification with missing data, used in the numerical examples of Section 5.2, was kindly provided to us by Rik Pintelon. The research leading to these results has received funding from the European Research Council under the European Union’s Seventh Framework Programme (FP7/2007-2013) / ERC Grant agreement number 258581 “Structured low-rank approximation: Theory, algorithms, and applications”.

A Special case of affine structure

A commonly encountered special case of the affine structure is

\[ [\mathcal{S}(\hat{p})]_{ij} = S_{0,ij} + \hat{p}_{S_{ij}} \quad \text{for some } S_{ij} \in \{1, \ldots, n_p\}^{m \times n}. \]

(S)

In (S), each element of the structured matrix \( \mathcal{S}(p) \) is equal to the sum of the \( S_{ij} \)th element of the parameter vector \( p \) and the constant \( S_{0,ij} \). The structure is then specified by the matrices \( S_0 \) and \( S \). Although (S) is a special case of the general affine structure (\( \mathcal{S} \)), it covers many linear modeling problems and will therefore be used in the implementation of the solution method.

In the implementation of the algorithm, the matrix \( S \) corresponds to a variable \( \text{tts} \). Given the matrix \( S \), specifying the structure, and a structure parameter vector \( \hat{p} \), the structured matrix \( \mathcal{S}(\hat{p}) \) is constructed by \( dh = s0 + \hat{p}(\text{tts}) \). The matrix dimensions \( m, n \), and the number of parameters \( n_p \) are obtained from \( S \) as follows:

\[
\begin{align*}
24a\quad & \langle S \mapsto (m,n,n_p) \rangle \\
& [mp, np] = \text{size}(\text{tts}); np = \max(\max(\text{tts})); \\
& \text{if exist('phi', 'var') && ~isempty(phi), m = size(phi, 1); else m = mp; end}
\end{align*}
\]

The transition from the specification of (S) to the specification in the general affine case (\( \mathcal{S} \)) is done by

\[
\begin{align*}
24b\quad & \langle S \mapsto \text{tts} \rangle \\
& \text{vec_tts} = \text{tts}(:,); \text{NP} = 1:np; \\
& \text{bfs} = \text{vec_tts}(:, \text{ones(1, np))} = \text{NP(ones(mp * n, 1), :));}
\end{align*}
\]

\( \mathcal{S} \) is represented by the \( mn \times n_p \) matrix \( \text{bfs} \) in the code

\[ S := [\text{vec}S_1 \cdots \text{vec}S_{n_p}]. \]

Conversely, for an affine structure of the type (S), defined by \( S \) and \( (m, n) \), the matrix \( S \) is constructed by

\[
\begin{align*}
24c\quad & \langle S \mapsto \text{tts} \rangle \\
& \text{tts} = \text{reshape}(\text{bfs} * (1:np)', mp, n);
\end{align*}
\]
For compatibility with the software package for mosaic-Hankel matrices [26], we consider structures of the form $\Phi \mathcal{S}$, where $\Phi$ is a full row rank matrix and $\mathcal{S}$ is an affine structure. The default value for $\Phi$ is the identity matrix $I_m$.

$$\langle \text{default } \phi \rangle \equiv \begin{array}{l}
\text{if \sim exist('phi', 'var') | isempty(phi), phi = eye(size(tts, 1)); end}
\end{array}$$  \hspace{1cm} (7.11b)
